## The System Clock

Tick-tock tick-tock tick-tock

2

### The System Clock

- The rate in which instructions are executed is controlled by the CPU clock
- The faster the clock rate, the faster instructions will be executed
- Measured in Hertz – number of oscillations per second

Spring 2022

Computer Systems - CS-438-01

3

3

### The Clock

- Computers are typically (and generically) labeled on the processor clock rate
- In the early 80's it was about 1 Megahertz – million clocks per second
- Now, it is terms of Gigahertz – billion clocks per second

Spring 2022

Computer Systems - CS-438-01

4

4

### Clock and Instructions

- Not all instructions are "equal"
- Some require multiple clock cycles to execute
- For example:
  - add can take a single clock
  - but floating-point math could require a dozen

## von Neumann Architecture

The Information Superhighway

6

## von Neumann Machine Architecture

- Modern computers are based on the design of John von Neumann
- His design greatly simplified the construction of (and use) computers

Spring 2022

Background: State - Cook - CSU 35

7

7

## Some von Neumann Attributes

1. Programs are stored and executed in memory
2. Separation of processing from memory
3. Different system components communicate over a shared bus

Spring 2022

Background: State - Cook - CSU 35

8

8

## The Bus

- Electronic pathway that transports data between components
- Think of it as a "highway"
  - data moves on shared paths
  - otherwise, the computer would be very complex

Spring 2022

Background: State - Cook - CSU 35

9

9

## System Bus

- The information sent on the memory bus falls into 3 categories
- Three sets of signals
  - address bus
  - data bus
  - control bus

Spring 2022

Background: State - Cook - CSU 35

10

10

## Address Bus

- Used by the processor to access a specific piece of data
- This "address" can be
  - a specific byte in memory
  - unique IO port
  - etc...
- The more bits it has, the more memory can be accessed

Spring 2022

Background: State - Cook - CSU 35

11

11

## Address Bus Size Examples

- 8-bit  $\rightarrow 2^8 = 256$  bytes
- 16-bit  $\rightarrow 2^{16} = 64$  KB (65,536 bytes)
- 32-bit  $\rightarrow 2^{32} = 4$  GB (4,294,967,296 bytes)
- 64-bit  $\rightarrow 2^{64} = 18$  EB (18,446,744,073,709,551,616)

Spring 2022

Background: State - Cook - CSU 35

12

12

## Historic Address Sizes

- Intel 8086
  - original 1982 IBM PC
  - 20-bit address bus (1 MB)
  - only 640 KB usable for programs
- MOS 6502 computers
  - Commodore 64, Apple II, Nintendo, etc...
  - 16-bit address bus (64 KB)

Spring 2022

Background: State - Cook - CSU 35

13

13

## Data Bus

- The actual data travels over the *data bus*
- The number of bits that the processor uses – as its natural unit of data – is called a *word*

Spring 2022

Background: State - Cook - CSU 35

14

14

## Data Bus

- Typically we define a system by word size
- Example:
  - 8-bit system uses 8 bit words
  - 16-bit system uses 16 bits (2 bytes) words
  - 32-bit system uses 32 bits (4 bytes) words
  - etc...

Spring 2022

Background: State - Cook - CSU 35

15

15

## Control Bus

- The *control bus* controls the timing and synchronizes the subsystems
- Specifies what is happening
  - read data
  - write data
  - reset
  - etc...

## von Neumann Architecture Today

- Because of the emphasis on memory, most real-world systems use a modified version of his design
- In particular, they have a special high-speed bus between the processor and memory

Spring 2022      Sacramento State - CSIS - CSIS 35      20

20

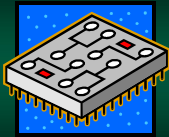

## von Neumann Architecture Today

- Think of it as a diamond-lane on a freeway
- ... or as high-speed rail – which has a fixed source and destination and goes faster than the freeway

Spring 2022      Sacramento State - CSIS - CSIS 35      21

21

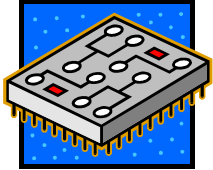

## Technological Trends

Change is fast

22

## Technological Trends

- Since the design of the integrated circuit, computers have advanced *dramatically*
- Home computer's today have more power than mainframes did 30 years ago
- A hand calculator has more power than the computer that took us to the Moon

Spring 2022      Sacramento State - CSIS - CSIS 35      23

23

## Integrated Circuits Improved In...

- *Density* – total number transistors and wires can be placed in a fixed area on a silicon chip
- *Speed* – how quickly basic logic gates and memory devices operate
- *Area* – the physical size of the largest integrated circuit that can be fabricated

Spring 2022      Sacramento State - CSIS - CSIS 35      24

24

## Rate of Improvement

- The increase in performance does not increase at a linear rate
- Speed & Density improves exponentially
  - from one year to the next... it has been a relatively constant fraction of the previous year's performance
  - ...rather than constant absolute value

Spring 2022

Baroness, State - Cook - CSC 35

25

25

## Moore's Law

- Gordon Moore is one of the co-founders of Intel
- He first observed (and predicted) computer performance improves exponentially, not linearly

Spring 2022

Baroness, State - Cook - CSC 35

26

26

## Moore's Law

- Moore's Law states the performance doubles every 18 months
- This law has held for nearly 50 years

27

## Moore's Law - The number of transistors on integrated circuit chips (1971-2018)

Moore's law describes the empirical regularity that the number of transistors on integrated circuits doubles approximately every two years. This advancement is important as other aspects of technological progress - such as processing speed or the price of electronic products - are linked to Moore's law.

## CISC vs. RISC

How do we tip the scales?

## CISC vs. RISC

- There is, an often contentious, debate on how to design a processor
- For instance:
  - how is memory going to be accessed
  - what instructions are needed
  - how to encode/structure them

Spring 2022

Baroness, State - Cook - CSC 35

30

30

## CISC vs. RISC

- Typically, the debate comes down to CISC vs. RISC
- Processors are typically put into these two categories
- Rarely is a processor "pure" RISC or CISC
- It's a *design philosophy* with a large "gray" area

Spring 2022

Background: State - Cook - CSU 38

31

31

## Hardware vs. Software

Spring 2022

Background: State - Cook - CSU 35

32

32

## RISC

- Reduced Instruction Set Computer (RISC) emphasizes simplicity
- Software should contain the complexity rather than hardware

Spring 2022

Background: State - Cook - CSU 35

33

33

## RISC – Simple Hardware

Spring 2022

Background: State - Cook - CSU 35

34

34

## RISC

- So, RISC contains fewer instructions than CISC – only the minimum needed to work
- Minimize memory access
  - only a few instructions can access memory
  - usually limited to register load and store instructions

Spring 2022

Background: State - Cook - CSU 35

35

35

## RISC Characteristics

- Access to memory is restricted to load/store instructions
- Many registers – since all instructions can only use registers for calculations

Spring 2022

Background: State - Cook - CSU 35

36

36

## RISC Characteristics

- Instructions typically take one clock cycle each
- The number of bytes, used by instructions, tend to fixed in size (all 32-bit, for example)

Spring 2022

Background: State - Cook - CSU 35

37

37

## RISC Advantages

- Simpler instructions simplify hardware - makes processors easier to manufacture
- Also, produces less heat and requires less energy

Spring 2022

Background: State - Cook - CSU 35

38

38

## RISC Advantages

- Fewer instructions means there is less to learn and master
- Memory access is minimized

Spring 2022

Background: State - Cook - CSU 35

39

39

## Example RISC Processors

- ARM
  - dominant processor used by smartphones
  - designed to reduce transistors
  - less cost, less heat, less power
- IBM PowerPC 601
  - developed in by IBM, Apple, and Motorola (AIM)
  - used by 1990's Macs

Spring 2022

Background: State - Cook - CSU 35

40

40

## CISC

- Complex Instruction Set Computer (CISC) emphasizes flexibility in instructions
- Hardware should contain the complexity rather than the software

Spring 2022

Background: State - Cook - CSU 35

41

41

## CISC – Hardware is more complex

Spring 2022

Background: State - Cook - CSU 35

42

42

## CISC Characteristics

- Instructions can take multiple clocks – depending on how complex
- Operands are *generalized* – each can access memory, immediates or registers

Spring 2022

Baroness State - Cook - CSU 35

43

43

## CISC Characteristics

- Very few general-purpose registers
- The number of bytes, used by instructions, tend to vary in sizes

Spring 2022

Baroness State - Cook - CSU 35

44

44

## CISC Advantages

- Generally, requires fewer instructions than RISC to perform the same computation
- Software is easier to write given the flexibility

Spring 2022

Baroness State - Cook - CSU 35

45

45

## CISC Advantages

- Programs written for CISC architectures tend to take less space in memory
- Variable-sized instructions can make it possible for the processor "evolve" – i.e. add new instructions

Spring 2022

Baroness State - Cook - CSU 35

46

46

## Example CISC Processors

- Intel x86
  - evolved from the 8088 processor and contains 8-bit, 16-bit, and 32-bit instructions
  - dominant processor for PCs
- Motorola 68000
  - used in many 80's computers
  - ...including the first Macintosh

Spring 2022

Baroness State - Cook - CSU 35

47

47

## Example CISC Processors

- VAX
  - contained even more addressing modes than we will cover
  - specialized instructions – even case blocks!
  - supported data types beyond float and int: variable-length strings, variable-length bit fields, etc...

Spring 2022

48

48

## RISC vs. CISC Comparison

CISC	RISC
Emphasis on hardware complexity	Emphasis on software complexity
Most operands can access memory	Load/Store instructions can access memory
Low number of registers	Higher number of registers
Instructions can have multiple clock cycles	Instructions tend towards one per clock cycle
Encoded instructions vary in size	Encoded instructions are all the same size

49

## CISC Example (not x86)

```
# n = a * (b + c) - d

mov  R1, b
add  R1, c      # b + c

mul  R1, a      # a * (b + c)
sub  R1, d      # a * (b + c) - d

mov  n, R1
```

50

## RISC Example (not x86)

```
# n = a * (b + c) - d

load R1, b
load R2, c
add  R2, R1     # b + c
load R3, a
mul  R2, R3     # a * (b + c)
load R4, d
sub  R2, R4     # a * (b + c) - d
store n, R2
```

51

## Moore's Law & CISC

The pendulum swings

52

## Moore's Law & CISC

- In the early 80's (the beginning of the Computer Revolution), memory was *expensive*
- In fact, it was the most expensive part of a new computer

53

## Moore's Law & CISC

- Memory also ran at the same speed as the processor
- So, CISC was at a clear advantage – programs didn't take up as much memory as RISC

54

## Moore's Law & CISC

- Computer speed through the 1980's grew exponentially
- However, ...
  - rate of processor growth has been far greater than memory
  - so, memory *relative to the processor's speed* has gotten much slower

Spring 2022

Background: State - Cook - CSU 38

55

## Moore's Law During the 80's

Spring 2022

Background: State - Cook - CSU 35

56

## Memory is the Bottleneck

- CISC can access memory with nearly every instruction
- Memory is slow compared to register-to-register operations
- It is far more efficient (now) to do all work on the processor and use memory only when absolutely necessary

Spring 2022

Background: State - Cook - CSU 35

57

## Latest Approach

- After the 1990s, RISC architectures have incorporated some of most useful complex instructions from CISC architectures
- Rely on their micro-architecture to implement these instructions with little impact on the clock cycle

Spring 2022

Background: State - Cook - CSU 35

58

## Instruction Operands

How much data does each need?

## Instruction Operand

- The number of operands used in an instruction varies greatly by processor
- More operands give greater functionality, but require more bits to store in memory
- Typically processors contain 1, 2 or 3 operands

Spring 2022

Background: State - Cook - CSU 35

60

## Single Operand Processors

- Single operand processors are also known as *accumulators*
- Operates similar to your hand calculator
- The accumulator register
  - used for all mathematical computations
  - other registers simply are used to compare and hold temporary data
- Examples: MOS 6502

61

## Single Operand Instruction (CISC)

```
# z = 50 - (x + y)

lda x
add y      # x + y
sta temp
lda 50
sub temp   # 50 - temp

sta z
```

lda = Load accumulator

sta = store accumulator

62

## Two Operand Processors

- Allows two operands to be specified
- For computations, both operands are typically treated as input, and one is used to store the result
- Examples:
  - x86 processors
  - PowerPC

63

## Two Operand Instruction (CISC)

```
# z = 50 - (x + y)

mov R1, x
add R1, y    # x + y

mov R2, 50
sub R2, R1   # 50 - R1

mov z, R2
```

64

## Three Operand Processors

- Allows two input values like before, but also can specify a third output operand
- The third operand can also be used as a index for simple addressing
- Examples:
  - ARM
  - Intel Itanium

65

## Three Operand Instruction (RISC)

```
# z = 50 - (x + y)

load R1, x
load R2, y
add R3, R1, R2    # x + y
load R4, 50
sub R5, R4, R3
store z, R5
```

66

## Three Operand Instruction (CISC)

```
# z = 50 - (x + y)
add R1, x, y      # x + y
sub z, 50, R1
```
